VERNAL POOLS ARE...

- Non-tidal ephemeral wetlands
- Supplied by precipitation or ground water
- Typically not mapped or protected
- Lacking in predatory fish populations
- Critical breeding habitat for fairy shrimp, wood frogs, marbled & spotted salamanders

What do Vernal Pools look like?

Upland Isolated

Floodplain &
Wetland Complexes

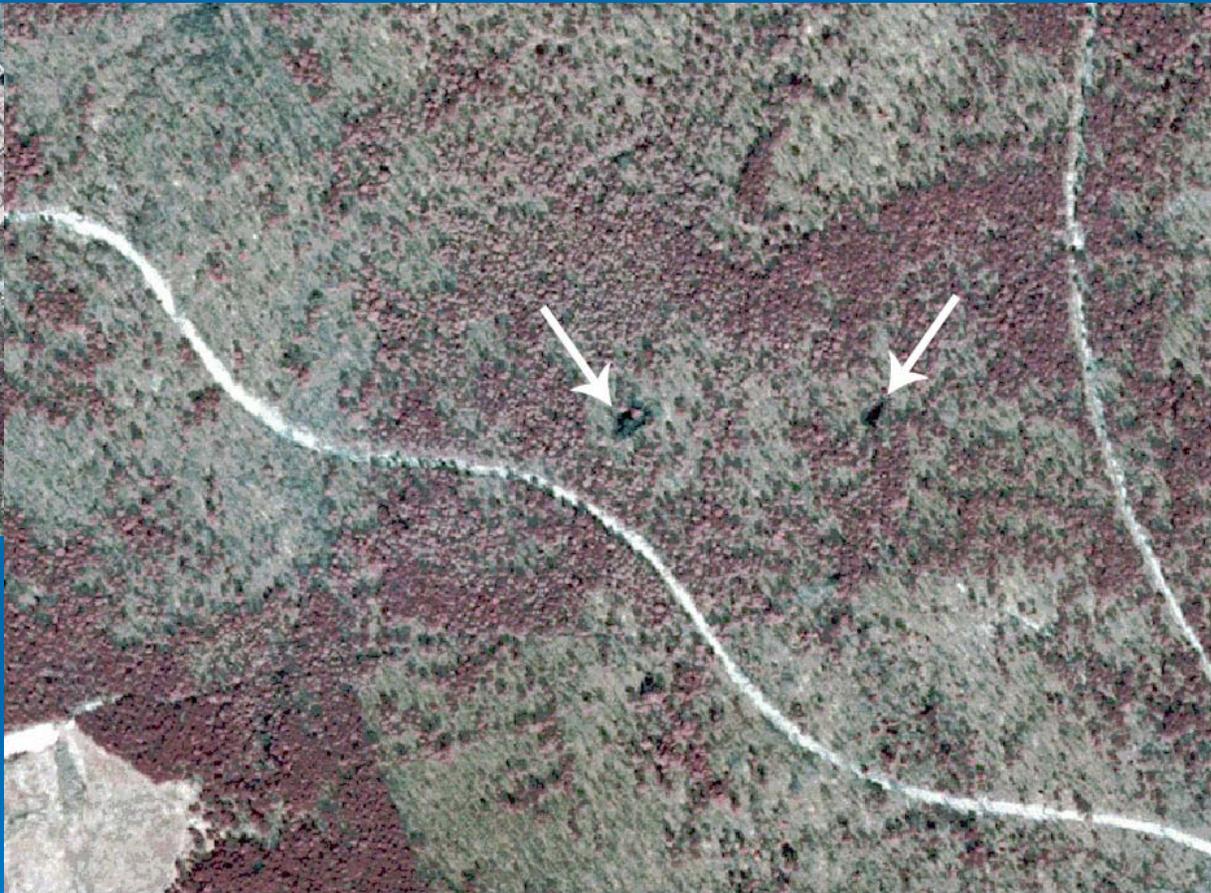

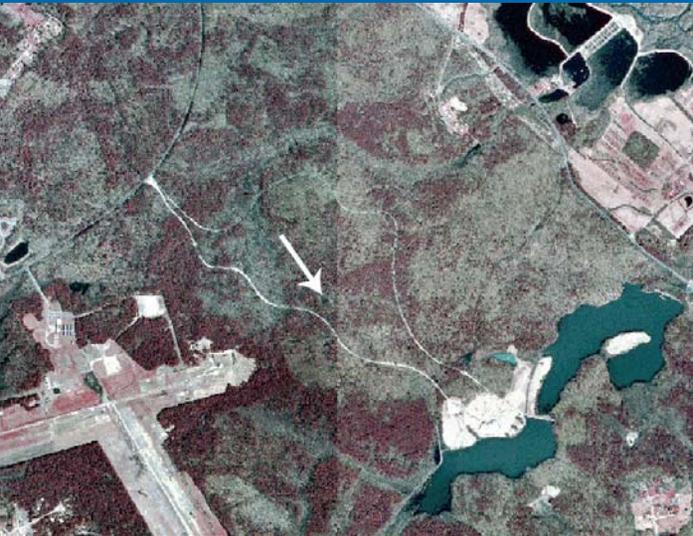

Roadside Ditch

4/2/2002

4/29/2002

Finding Vernal Pools

Aerial Photos or Color Infrared DOQQs
Ground-truthing

Wood frog (*Rana sylvatica*)

“...egg-mass counts may be an effective means to monitor wood frog populations, as it is a relatively accurate and precise survey technique.” (Crouch & Paton 2000)

Spotted salamander (*Ambystoma maculatum*)

“Because the spotted salamander is so widespread and well studied, it would make an excellent focal species for use in long-term amphibian monitoring programs.” (Petranka 1998)

Breed February-May

Eggs for 1-4 week window

1 egg mass per female

Eggs often laid in
communal rafts

Attached to vegetation

Near water surface

Breed March-June

Eggs for 4-7 week window

2-4 egg masses per female

Eggs laid individually or in
communal aggregates

Attached to vegetation

Typically deeper in water

Goals of Vernal Pool Study

To estimate wood frog & spotted salamander abundance using egg mass counts & presence using a proportion of area occupied (PAO) approach for the purpose of drawing inferences about variation over time (population trends) & space (relationships with landscape & environmental variables).

In This Talk...

- Spatial sampling and detectability issues
- Describe double-observer dependent egg mass estimation technique

PRELIMINARY ANALYSES

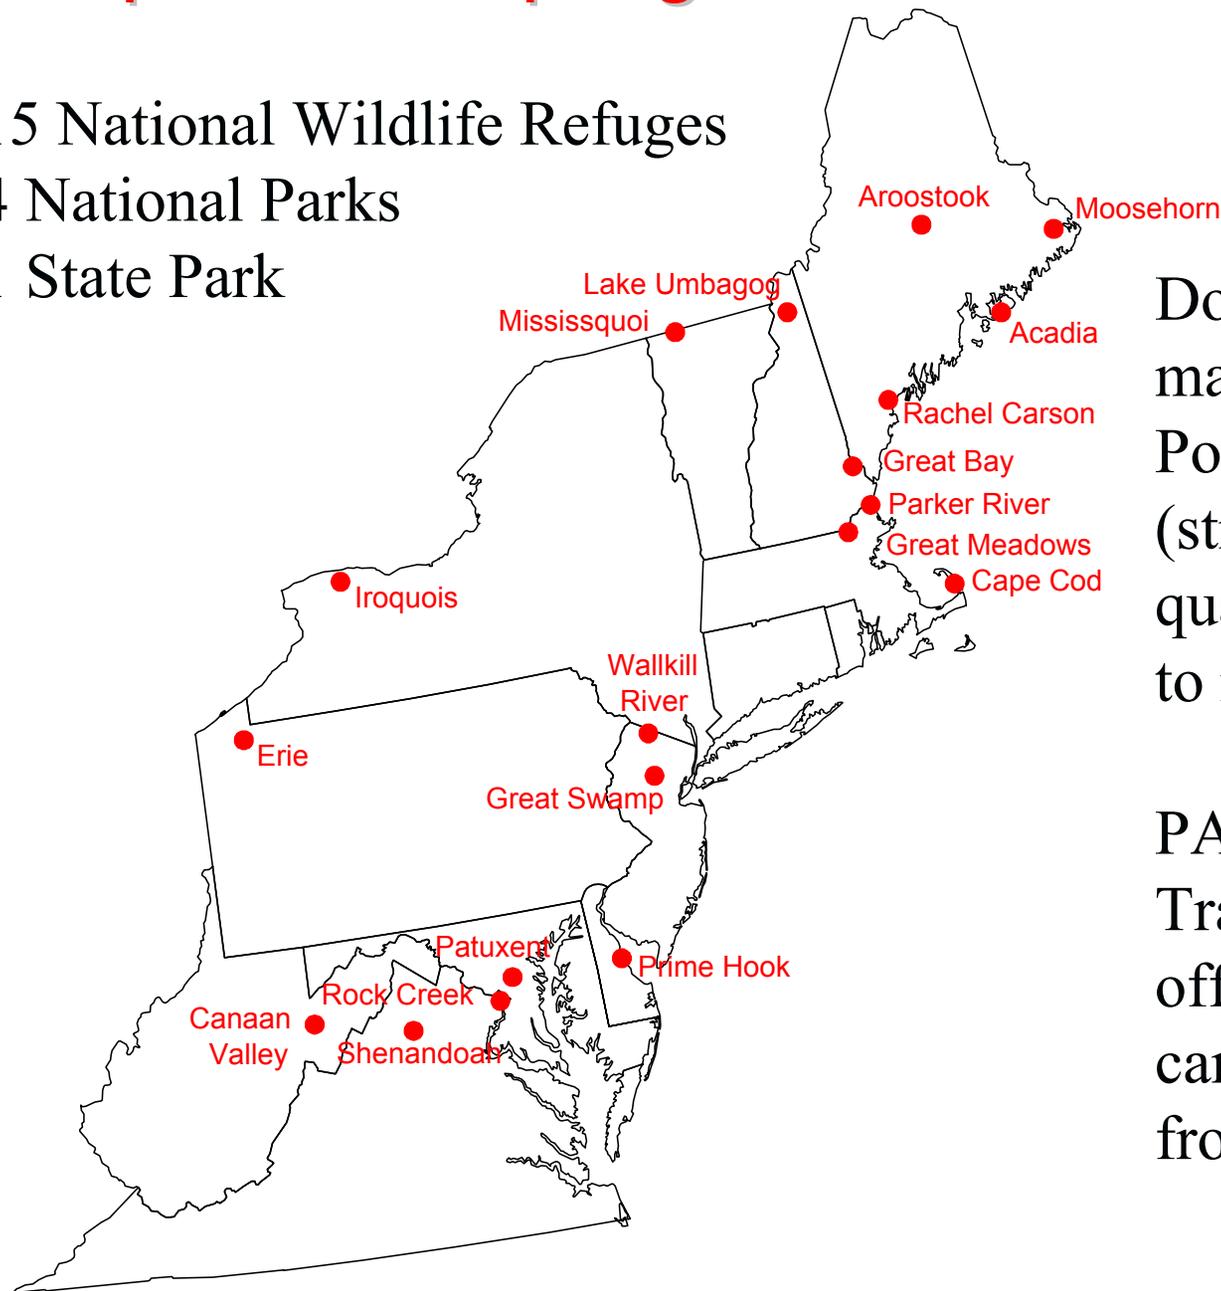

- Examine covariates that might influence detectability and abundance of wood frog & spotted salamander egg masses
- Examine covariates that might influence site occupancy and detectability of wood frogs and spotted salamanders

Spatial Sampling: DOI Lands in the NE US

15 National Wildlife Refuges

4 National Parks

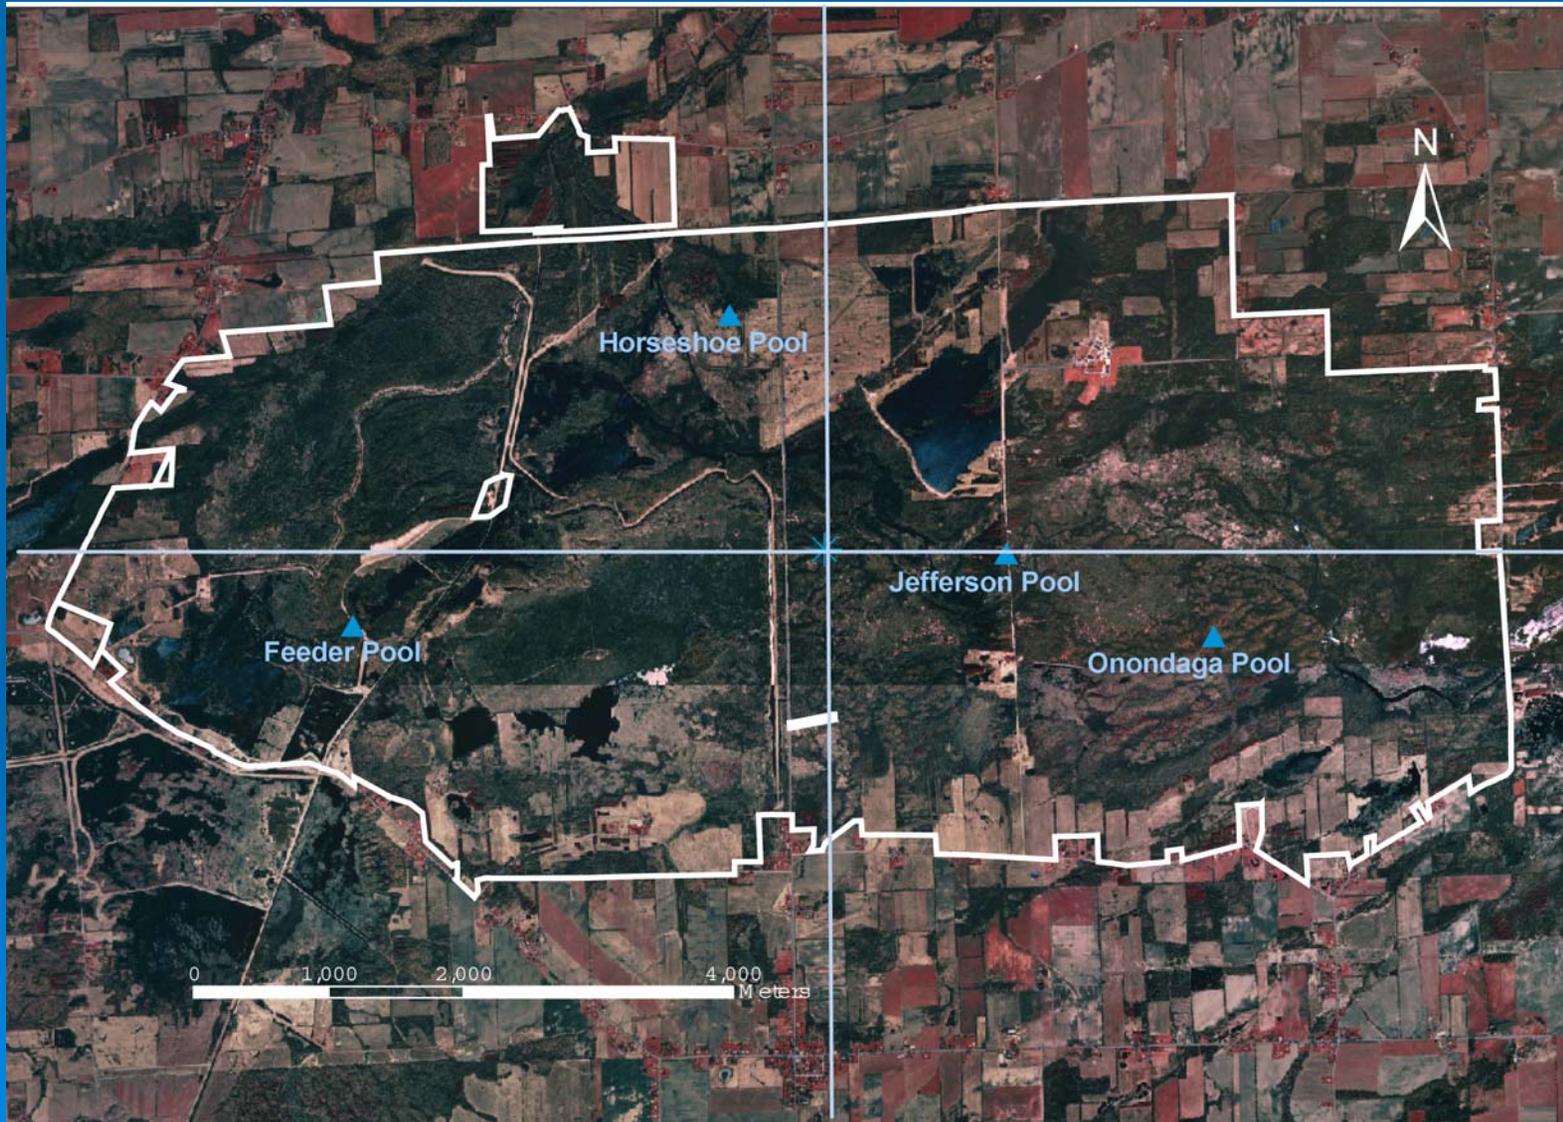

1 State Park

Double-observer egg mass counts at 4 Focal Pools per DOI land (stratified selection by quadrant & proximity to road)

PAO at Focal Pools & Transect Pools found off 250 m transects in cardinal directions from Focal Pools

Iroquois National Wildlife Refuge

Estimation of N Requires Estimation of Detectability

$$E(C) = Np$$

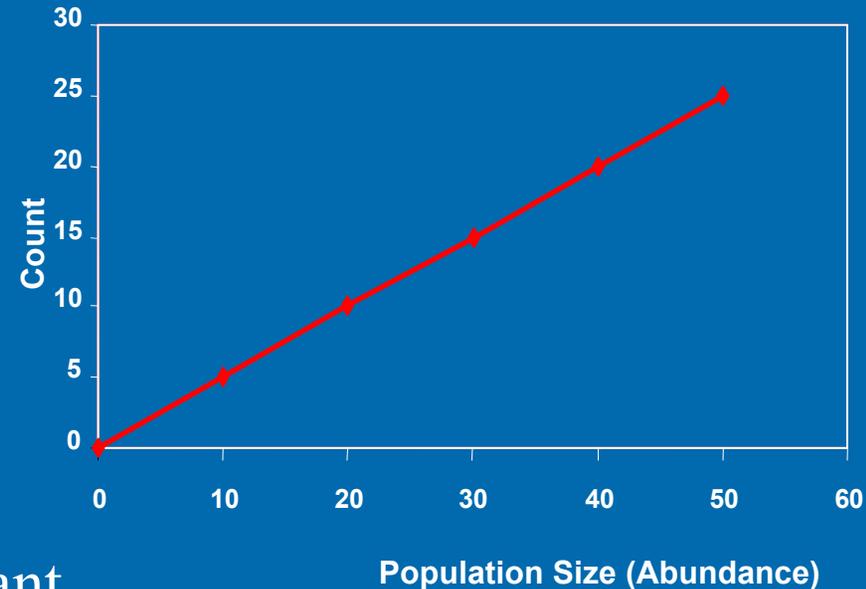

With unadjusted count data,
one assumes a linear relationship
between C and N and that p is constant

C = Count statistic (what we collect)

N = True abundance (population size
unknown)

p = Detection probability (probability that a
member of N appears in C)

Proportional or Linear Relationship

Double-Observer Dependent Egg Mass Estimation Technique

- Two Observers (Obs) survey pool together
- Obs 1 points out egg mass areas & numbers of egg masses per area to Obs 2
- Obs 2 records Obs 1's counts & records any other areas & egg masses that Obs 1 missed
- Observers switch halfway around pool

**Each pool surveyed at least twice during peak breeding season
to obtain estimates of maximum abundance**

Double-Observer Dependent

(Nichols *et al.* 2000)

Enter Data into Program DOBSERV

<http://www.mbr-wrc.usgs.gov/software/dobserv.html>

Observers: Sally Mander = 1, Woody Frog = 2

A. Spotted salamander detection probability increases with distance from a road

B. Wood frog detection probability varies by sampling occasion

| *c(hat) | 3.79 | | | | |

CONCLUSIONS

- Estimation of egg mass numbers in pools essential because detection probabilities (p 's) vary spatially (and perhaps temporally)
- More spotted salamander egg masses at larger vernal pools; wood frog egg mass counts differed at pools differing in acid-neutralizing capacity
- Spotted salamander detectability higher at pools further from a road and site occupancy influenced by pool area and pool depth
- Wood frog detectability higher earlier in season
- Coming Soon: GIS landscape analyses
