Smithsonian Institution, Washington, D.C. 20013-7012, U.S.A., e-mail: woodmann@si.edu

Abstract.—The twelve recognized species of nectar-feeding bats of the genus *Lonchophylla* occur in low- and middle-elevation, humid, Neotropical forests. Morphological and morphometrical analyses of specimens formerly lumped with *Lonchophylla mordax* O. Thomas (1903) support recognition of *Lonchophylla concava* Goldman (1914) as a separate species and reveal a third species from the western Pacific lowlands of Colombia and Ecuador that I describe herein as *Lonchophylla fornicata*. This new species is morphologically similar to *Lonchophylla concava* but is distinctively larger than that species. Tests for sexual dimorphism within these and other species of Lonchophyllini suggest a tendency for females to have slightly longer, narrower skulls, higher coronoid processes of the mandible, and longer forearms than males.

The genus *Lonchophylla* includes twelve species of nectar-feeding bats that are distributed primarily in tropical, low- to mid-elevation forests from southern Nicaragua south to southern Peru, Bolivia, and southeastern Brazil (Koopman 1994, Dávalos 2004, Albuja & Gardner 2005, Woodman & Timm 2006). Recent phylogenetic analyses confirm a close relationship among *Lonchophylla* and the monotypic genera *Lionycteris*, *Platalina*, and *Xeronycteris* (Dávalos & Jansa 2004, Gregorin & Ditchfield 2005, Woodman and Timm 2006), which together comprise a specialized monophyletic lineage (tribe Lonchophyllini) within the phyllostomid subfamily Glossophaginae (Wetterer et al. 2000, Carstens et al. 2002, Baker et al. 2003, Gregorin & Ditchfield 2005, Simmons 2005). In fact, molecular and combined molecular and morphological analyses indicate that *Lonchophylla* may be paraphyletic with respect to one or more of these other three genera (Baker et al. 2003, Dávalos and Jansa 2004, Gregorin & Ditchfield 2005). De-

spite these possible relationships, the four genera as currently understood are easily distinguished from one another using suites of morphological characters (Woodman & Timm 2006).

While investigating variation within and among species of Lonchophyllini in order to better understand and describe *Lonchophylla cadenai* and *Lonchophylla pattoni* (Woodman & Timm, 2006), I encountered specimens of a distinctive *Lonchophylla* from the Pacific lowlands in southwestern Colombia and northwestern Ecuador. These specimens represent a previously unrecognized species that is most similar morphologically to, but distinct from, *Lonchophylla concava* (Goldman, 1914). Herein, I describe this new species and explain its relationships with other species in the genus.

Materials and Methods

Measurements (mm) follow those of Woodman & Timm (2006), who described and illustrated the skull dimen-

sions used herein. Forearms and skulls were measured to the nearest 0.1 mm using a digital caliper or an ocular micrometer in a dissecting microscope. With the exception of length of forearm, external measurements are those recorded by the original collectors. Length of head and body was determined by subtracting tail length from total length. Length of forearm was measured from the elbow to the distal-most extension of the bent wrist. Abbreviations used for measurements are provided in Table 1. Capitalized color terms are those of Ridgway (1912). In descriptions of habitats, capitalized vegetational associations are from the Holdridge system for classification of life zones (Holdridge 1947, Holdridge et al. 1971). Specimens examined for this study are listed in Appendix I.

The new species that I describe herein is most similar in size and morphology to *Lonchophylla concava* Goldman (1914), and specimens of the new species were initially identified as belonging to that species (e.g., Woodman & Timm 2006: 475). *Lonchophylla concava* generally has been treated as a subspecies of *Lonchophylla mordax* O. Thomas (1903) since Handley's (1966) study of Panamanian *Lonchophylla*. However, I agree with Albuja & Gardner's (2005) recognition of *L. concava* and *L. mordax* as distinct species. The two taxa are similar in size (Table 1) but differ in a number of qualitative skull characters (Woodman & Timm 2006).

In order to compare the new species with *L. concava* and to determine whether the former's larger size could be explained by clinal variation in *L. concava*, I carried out principal components analyses (PCA) using a correlation matrix of eight variables (GLS, PL, SB, ZB, UTL, LTL, CPH, FAL) and plotted the resulting scores. Because of the long time span during which *L. concava* and *L. mordax* were considered conspecific, I included *L. mordax* in some of these comparisons.

Variables for these analyses were measured from seven individuals of the new species from Colombia and Ecuador; 37 *L. concava* from Colombia ($n = 2$), Costa Rica (9), Ecuador (8), and Panama (18); and 23 *L. mordax* from Brazil.

To investigate sexual dimorphism in *L. concava*, *L. mordax*, and the new species, I compared selected variables within species using Student's *t*-tests for small samples of equal or unequal size, as appropriate (Sokal & Rohlf 1981). I plotted PCA factor scores of female and male *L. concava* separately for one of the analyses and inspected the plots for patterns of differentiation. In addition, I looked for common, albeit non-significant, patterns of sexual variation among my samples and among Woodman & Timm's (2006) samples of *Lionycteris spurrelli* and *Lonchophylla thomasi*.

I reinvestigated the phylogeny of the Lonchophyllini (*Lonchophylla*, *Lionycteris*, *Platalina*, *Xeronycteris*) using 64 characters in a dataset (Appendix II) modified slightly from that used by Woodman & Timm (2006). This dataset included 26 morphological and mDNA restriction site characters from Wetterer et al.'s (2000) analysis of the Phyllostomidae. One major departure from Woodman & Timm's (2006) dataset was the deletion of their character 57, which was redundant with regard to characters 54–56. In addition, I was able to code selected characters not previously provided for *L. bokermanni* from a single specimen (TTU 43627). Because previous analyses of the Phyllostomidae (Baker et al. 2003, Wetterer et al. 2000, Carstens et al. 2002) suggested a variety of possible outgroup relationships for the Lonchophyllini, I included seven non-Lonchophyllini species of Phyllostomidae to polarize characters: *Anoura geoffroyi*, *Glossophaga soricina*, and *Monophyllus redmani* (Glossophaginae, Glossophagini); *Carollia perspicillata* (Carollinae); *Erophylla sezekorni* and *Phyllonycteris*

Table 1.—Skull and external measurements of males and females of three species of *Lonchophylla*. Statistics are mean \pm SD, with observed extremes. Abbreviations used for measurements are given in parentheses.

¹ Except as noted.

² Female *Lonchophylla fornicata* have a longer mean FAL than males ($t = 2.4495$; $df = 8$; $P < 0.05$). The differences between mean FAL for female and male *L. concava* ($t = 1.3785$; $df = 40$; $0.2 > P > 0.1$) and *L. mordax* ($t = 1.3147$; $df = 20$; $0.4 > P > 0.2$) are not statistically significant.

poeyi (Phyllonycterinae); and *Brachyphylla cavernum* (Brachyphyllinae). I used the computer program PAUP 4.0b10 for Macintosh computers (see Swofford 1998) to analyze the matrix. All characters were unordered and equally weighted. No topology for the out-groups was enforced. Parsimony analyses used the heuristic search option with a random addition sequence of 1000 replicates. Starting trees were via stepwise addition, and the branch-swapping algorithm was tree-bisection-reconnection (TBR). I also carried out bootstrap analyses of 1000 bootstrap repetitions with a random addition sequence of 100 replicates and TBR. Character evolution on the resultant trees was analyzed using MCCLADE 3.0 (Maddison & Maddison 1992).

I examined specimens (see Appendix I) from the following collections (abbreviations in parentheses): American Museum of Natural History, New York (AMNH); Carnegie Museum of Natural History, Pittsburgh (CM); Field Museum, Chicago (FM); University of Kansas Natural History Museum, Lawrence (KU); Los Angeles County Museum, Los Angeles (LACM); Louisiana State University Museum of Zoology, Baton Rouge (LSU); Museum of Southwestern Biology, Albuquerque (MSB); Michigan State University, East Lansing (MSU); Museum of Texas Tech University, Lubbock (TTU); National Museum of Natural History, Washington, D.C. (USNM).

Results

The twelve species of *Lonchophylla* currently recognized often are divided into two size groups based on greatest length of skull (GLS; Taddei et al. 1983, Dávalos 2004, Woodman & Timm 2006). GLS correlates poorly with other more typical proxies for body size, such as length of head and body or weight (Woodman & Timm 2006), and the size

division based on GLS does not reflect phylogenetic relationships within the genus as they are currently understood (e.g., Dávalos & Jansa 2004). The division into size groupings is generally useful, however, for characterizing species and identifying specimens (Woodman & Timm 2006). The “large” *Lonchophylla* (GLS $>$ 24.5 mm) are *L. bokermanni*, *L. choconana*, *L. handleyi*, *L. hesperia*, *L. orcesi*, and *L. robusta* (Table 1). “Small” species (GLS $<$ 24.5 mm) include *L. cadenai*, *L. concava*, *L. dekeyseri*, *L. mordax*, *L. pattoni*, and *L. thomasi*. The new species is intermediate in size (GLS = 23.7–25.4, Table 1) and overlaps both smaller individuals in the large size group (especially *L. bokermanni* and *L. hesperia*) and larger individuals from the small size group (especially *L. concava* and *L. mordax*).

Lonchophylla fornicate, new species

Pacific Forest Long-tongued Bat

Fig. 1

Glossophaga soricina: M. E. Thomas 1972:157 (part); not *Glossophaga soricina* (Pallas).

Lonchophylla mordax: McCarthy et al. 2000:958 (part); not *Lonchophylla mordax* O. Thomas.

Lonchophylla concava: Woodman & Timm 2006:475 (part); not *Lonchophylla concava* Goldman.

Holotype.—Dried skin and skull of adult male, National Museum of Natural History (USNM) number 483360, collected 18 November 1966 by Maurice Earl Thomas (original number 914). Skull in good condition; skin missing small patches of fur on posterior dorsum and a large patch of fur on posterior venter.

Type locality.—29 km SE of Buena-ventura, 75 m elevation, east bank of Río Zabaletas, across from the village of Zabaletas [3°44'N, 76°57'W—Paynter 1997], Valle del Cauca Department, Colombia.

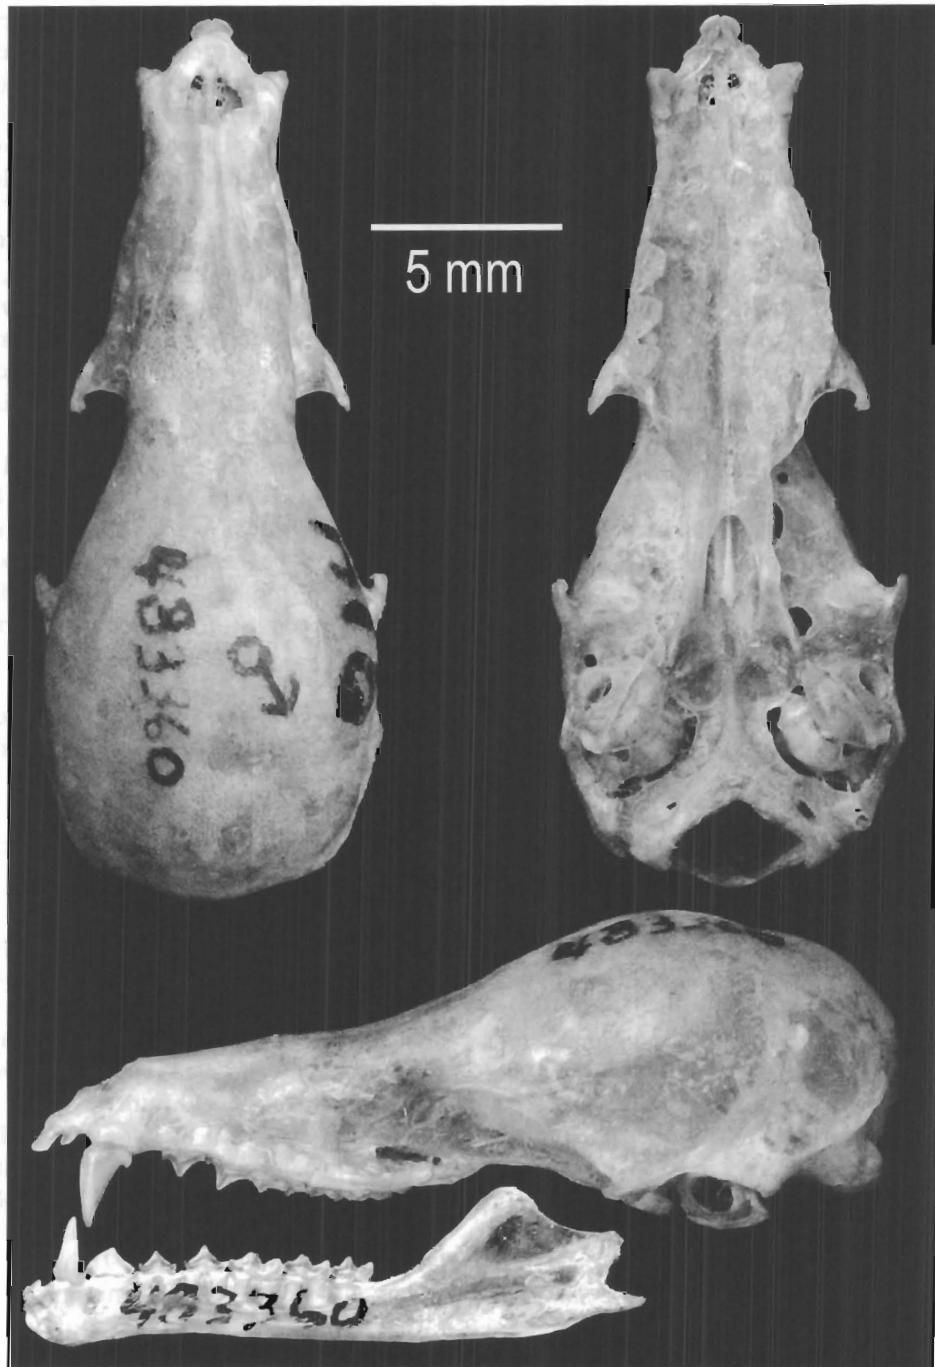

Fig. 1. Dorsal and ventral views of the cranium and lateral view of the cranium and mandible of *Lonchophylla fornicata*.

Referred specimens (9).—One male (USNM 446466) taken 17–19 Apr 1967 by M. E. Thomas (original number 925) at the type locality; 1 male (FM 89572) obtained 18 Feb 1959 by Kjell von Sneidern, and 4 females (one pregnant) and 2 males (LACM 18771–18776) collected 27–28 Aug 1959 by Melbourne Armstrong Carriker, Jr., at La Guayacana (ca. $1^{\circ}26'N$, $78^{\circ}27'W$), 225 m, Nariño Department, Colombia; 1 male (CM 112585) collected 28 Dec 1991 by T. J. McCarthy at the Lita train tunnel, ca. 1.7 km east of Lita train station (ca. $0^{\circ}52'N$, $78^{\circ}28'W$), 512 m, Imbabura Province, Ecuador.

Etymology.—The species name *fornicata* is a Latin adjective meaning “arched,” and it was chosen to communicate the similarity of the new species to *Lonchophylla concava* (*concava* being a Latin adjective meaning “hollowed,” “arched inward,” most likely in reference to the deeply arched posterior portion of the palate).

Distribution.—Known from the Pacific coastal plain of southwestern Colombia and northwestern Ecuador; elevational distribution from 75 m to just above 500 m (Fig. 2).

Diagnosis.—Based on GLS, *L. fornicata* is a medium-sized member of the genus, most easily distinguished from *L. choocoana*, *L. handleyi*, *L. hesperia*, *L. orcesi*, and *Platalina genovensium* by its shorter skull (GLS < 26.0), and from *Lonchophylla cadenai*, *L. dekeyseri*, *L. pattoni*, *L. thomasi*, and *Lionycteris spurrelli* by its longer skull (GLS > 23.0). *Lonchophylla fornicata* is further distinguished from *L. bokermanni*, *L. choocoana*, *L. handleyi*, *L. hesperia*, *L. orcesi*, and *Platalina genovensium* by its shorter forearm (FA < 36.5), and from *Lonchophylla cadenai* by its longer forearm (FA \geq 33.0). From other *Lonchophylla*, *L. fornicata* can be distinguished by its short, brown dorsal pelage (in contrast to those of *L. pattoni* and *L. robusta*); long,

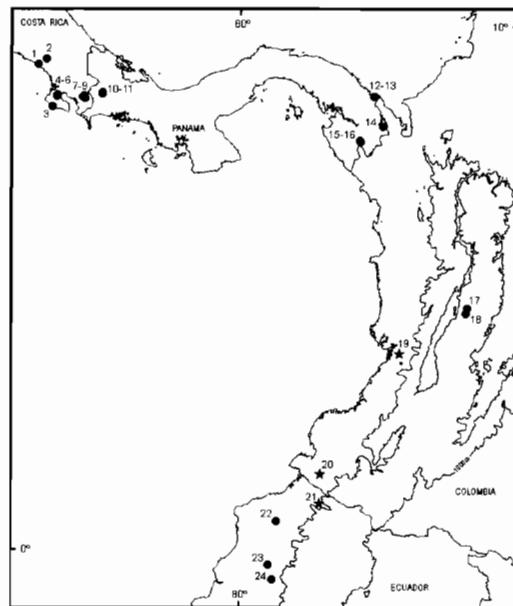

Fig. 2. Map of southern Central American and northwestern South America, illustrating the distribution of specimens of *Lonchophylla fornicata* (stars) and *L. concava* (dots).

narrow, uninflated rostrum (in contrast to those of *L. choocoana*, *L. dekeyseri*, *L. handleyi*, *L. hesperia*, *L. mordax*, *L. orcesi*, *L. robusta*); narrow, uninflated supraorbital region (in contrast to those of *L. cadenai*, *L. concava*, *L. handleyi*, *L. hesperia*, *L. pattoni*, *L. robusta*, *L. thomasi*) typically lacking distinct lateral projections (in contrast to *L. cadenai*, *L. robusta*); more posterior placement of posterior border of anteorbital foramen (in contrast to *L. bokermanni*, *L. cadenai*, *L. choocoana*, *L. mordax*, *L. pattoni*, *L. robusta*, *L. thomasi*) the outer margin of which does not project beyond the lateral outline of the rostrum (in contrast to *L. cadenai*, *L. pattoni*, *L. thomasi*); deeply grooved upper canine (in contrast to those of *L. choocoana*, *L. dekeyseri*, *L. handleyi*, *L. mordax*, *L. robusta*); P4 with obvious, rooted lingual cusp (in contrast to those of *L. cadenai*, *L. choocoana*, *L. dekeyseri*, *L. handleyi*, *L. mordax*, *L. orcesi*, *L. pattoni*, *L. robusta*, *L. thomasi*); deep depression along midline of posteri-

or portion of palate (in contrast to those of *L. cadenai*, *L. choocoana*, *L. dekeyseri*, *L. hesperia*, *L. mordax*, *L. pattoni*, *L. thomasi*); posterior position of posterior border of palate (in contrast to those of *L. dekeyseri*, *L. hesperia*, *L. mordax*); long, open, U-shaped to W-shaped mesopterygoid fossa, often with median posterior projection of palate (in contrast to those of *L. cadenai*, *L. pattoni*, *L. thomasi*); narrow, uninflated pterygoid processes (in contrast to those of *L. cadenai*, *L. pattoni*, *L. thomasi*); shallow basisphenoid pits (in contrast to those of *L. cadenai*, *L. choocoana*, *L. hesperia*, *L. mordax*, *L. pattoni*, *L. thomasi*) separated by a broad median septum (in contrast to those of *L. cadenai*, *L. pattoni*, *L. thomasi*); long, slender mandible (in contrast to those of *L. bokermanni*, *L. cadenai*, *L. choocoana*, *L. dekeyseri*, *L. handleyi*, *L. hesperia*, *L. mordax*, *L. orcesi*, *L. robusta*, *L. thomasi*) with low, rounded coronoid processes (in contrast to those of *L. cadenai*, *L. dekeyseri*, *L. hesperia*, *L. mordax*, *L. orcesi*, *L. pattoni*, *L. robusta*) and long articular process; p2 lacking posterior cusp (in contrast to those of *L. bokermanni*, *L. cadenai*, *L. choocoana*, *L. dekeyseri*, *L. handleyi*, *L. mordax*, *L. orcesi*, *L. robusta*, *L. thomasi*); gap between i2 and lower canine greater than long dimension of i2 (in contrast to *L. bokermanni*, *L. cadenai*, *L. choocoana*, *L. dekeyseri*, *L. handleyi*, *L. mordax*, *L. orcesi*, *L. robusta*, *L. thomasi*).

Description.—*Lonchophylla fornicata* is a medium-sized species in the genus as measured either by greatest length of skull or by head and body length, and it has a relatively short forearm (Table 1). Dorsal pelage is typically 5–7 mm long and strongly bicolored. The paler bases (ca. 70–80% of the length of the hairs) are creamy brown (Avellaneous to Drab) in color, in contrast to the pale- to medium-brown tips, which vary from Buffy Brown on lower back to Natal Brown near the head. Ventral pelage is generally mono-

colored and varies from Avellaneous to Wood Brown. Genal vibrissae are absent, and there are three interramal vibrissae. An indistinct central rib extends to tip of noseleaf. In dorsal view, the rostrum is long and narrow, and it is not inflated above M1s, resulting in nearly parallel lateral outlines. The supraorbital region is narrow, not inflated, and typically lacks lateral projections. The posterior border of the antorbital foramen is typically within the outline of the rostrum. In lateral view, the posterior border of the antorbital foramen is typically between P4 and M1. In palatal view, obvious gaps are present between I1 and I2. P4 lacks a rooted lingual cusp. The transition of the posterior palate to the postdental palate is interrupted by deep midline depression. That portion of the palate posterior to M3 is longer than M3. The posterior margin of the palate typically extends posterior to the optic foramen and is near the anterior edge of the sphenoidal fissure. The mesopterygoid fossa is long, open, and U-shaped or W-shaped anteriorly; the anterior border of the mesopterygoid fossa typically is modified by a median projection of palate. The pterygoid processes are relatively narrow, and are not inflated. The basisphenoid pits are shallow, and the intervening septum is broad with rounded edges. The mandible is long and relatively slender. The coronoid process is low (slightly above level of the articular condyle) and broadly rounded. The articular process is long. The lower second premolar (p2) lacks a posterior cusp (hypoconid). In dorsal view, the gap between i2 and the canine is typically greater than the long dimension of i2.

Comparisons.—*Lonchophylla fornicata* is readily distinguished from *Lonchophylla bokermanni*, *L. choocoana*, *L. handleyi*, *L. hesperia*, *L. orcesi*, and *L. robusta* by its much shorter forearm ($FA < 36.0$ —Table 1), and from *L. cadenai* by its longer forearm ($FA \geq 33.0$). It is

distinguished from *L. chocoana*, *L. händleyi*, *L. hesperia*, and *L. orcesi* by its shorter skull (*GLS* < 26.0), and from *L. cadenai*, *L. dekeyseri*, *L. pattoni*, and *L. thomasi* by its longer skull (*GLS* > 23.0). In several dimensions, *Lonchophylla fornicata* is most similar to *L. cadenai*, *L. concava*, *L. dekeyseri*, *L. mordax*, *L. pattoni*, and *L. thomasi*; additional comparisons with these taxa follow.

Lonchophylla cadenai, *L. pattoni*, and *L. thomasi*: In addition to its longer skull (*GLS* > 23.0), *L. fornicata* has a longer, narrower rostrum; narrower, less inflated supraorbital region; more posteriorly located posterior border of anteorbital foramen (typically between P4 and M1 rather than above P3 or P4) that does not project beyond the lateral outline of the rostrum; longer, narrower palate; lingual cusp on P4 lacking; a deep depression along midline of posterior palate; a long, open U-shaped or W-shaped mesopterygoid fossa, with median projection of palate; narrow, uninflated pterygoid processes; broader septum separating basisphenoid pits; more rounded coronoid process; posterior cusp on p2 lacking; greater gap between i2 and canine.

Lonchophylla concava: *Lonchophylla fornicata* is closest morphologically to this species, from which it differs in its longer skull, wider posterior palate (as measured by MMB), and proportionally greater zygomatic breadth (Fig. 3A), supraorbital breadth, and lengths of maxillary and mandibular toothrows (Fig. 3B); longer maxillary toothrow relative to mandibular toothrow (Fig. 3C); greater height of coronoid process relative to mandibular toothrow (Fig. 3D).

Lonchophylla dekeyseri: In addition to its longer skull (*GLS* > 23.0), *L. fornicata* has a longer, narrower, and less inflated rostrum; more posteriorly located posterior border of anteorbital foramen (typically between P4 and M1 rather than above posterior root of P4); longer, broader palate; lingual cusp on P4 lack-

ing; a deep depression along midline of posterior palate; shallower basisphenoid pits; lower, more rounded coronoid process; posterior cusp on p2 lacking; greater gap between i2 and canine.

Lonchophylla mordax: *Lonchophylla fornicata* has a longer, narrower, less inflated rostrum; more posteriorly located posterior border of anteorbital foramen (typically between P3 and M1 rather than between anterior and posterior roots of P4); longer, broader palate; lingual cusp on P4 lacking; a deep depression along midline of posterior palate; shallower basisphenoid pits; lower, more rounded coronoid process; posterior cusp on p2 lacking; greater gap between i2 and canine.

Multivariate analysis.—A plot of factor scores from a PCA comparing *L. concava*, *L. fornicata*, and *L. mordax* (Fig. 4) shows that *Lonchophylla concava* and *L. mordax* overlap nearly completely on PC 1, which represents overall size (Table 2). In contrast, *L. fornicata* typically is larger than either of those species. Along PC 2, *L. mordax* is almost entirely separated from *L. concava* and *L. fornicata*, reflecting its generally shorter palate, narrower supraorbital region, higher coronoid process, and longer forearm (Table 2).

A plot of factor scores from a second PCA comparing just *L. concava* and *L. fornicata* (Fig. 5), shows the two species separate along PC 1, which emphasizes the greater size of *L. fornicata* (Table 3). Despite the wide distribution of specimens, from southern Costa Rica through western Ecuador, *L. concava* is relatively uniform in size, with no indication of clinal variation. Specimens of *L. fornicata* have a size distribution that is nearly as great as that of *L. concava* despite their more limited geographic range. Along PC 2 ("length" vs. "breadth;" see Table 3), the two species overlap considerably, although *L. fornicata* has a much narrower range of variation. Within *L. concava*, there appears to be a tendency

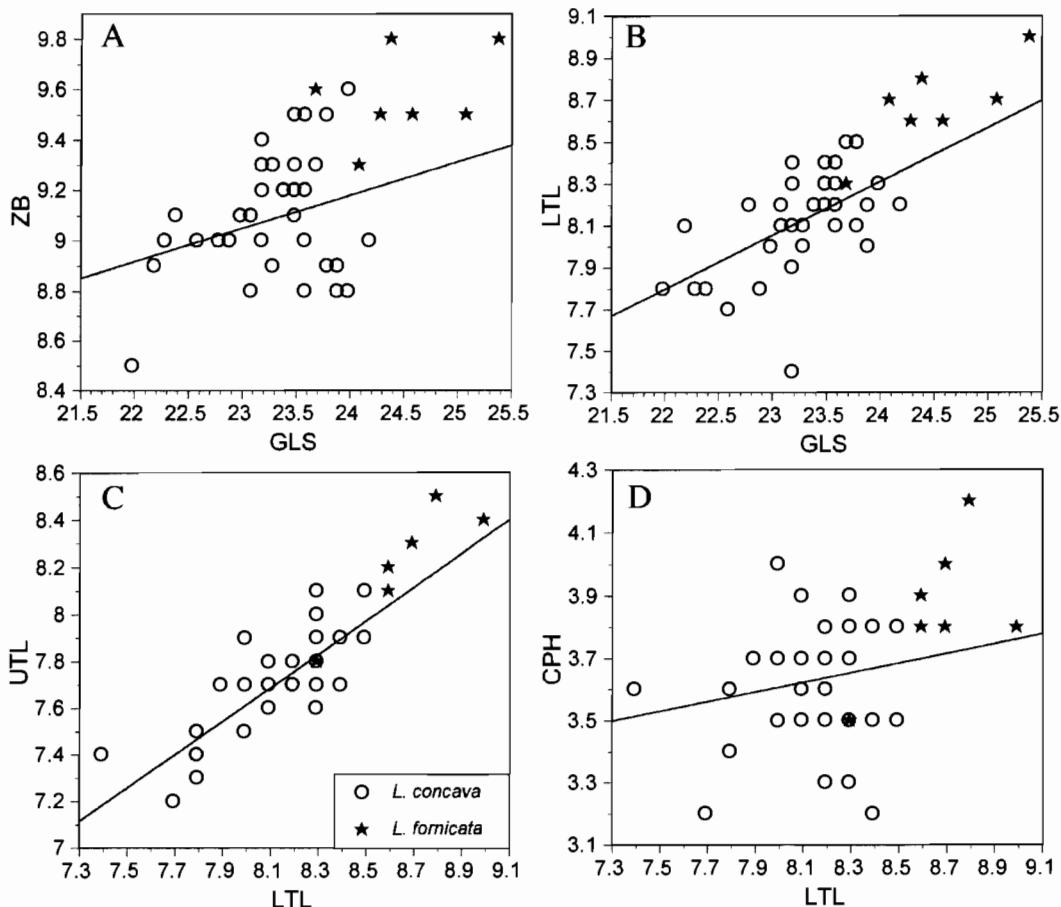

Fig. 3. Bivariate plots of variables measured from *L. concava* and *L. fornicata*. Abbreviations are explained in Table 1. Regressions are based only on *L. concava* and are extended through plots of *L. fornicata*. A, Bivariate plot of zygomatic breadth (ZB) and greatest length of skull (GLS), illustrating the longer and relatively broader skull of *L. fornicata* ($ZB = 6.03 + 0.131 \text{ GLS}$; $F = 2.91$, $p = 0.097$). B, Bivariate plot of length of mandibular toothrow (LTL) and greatest length of skull (GLS), illustrating the longer skull and relatively longer toothrow of *L. fornicata* ($LTL = 2.16 + 0.256 \text{ GLS}$; $F = 16.71$, $p = 0.000$). C, Bivariate plot of length of maxillary toothrow (UTL) and length of mandibular toothrow (LTL), illustrating both the longer maxillary and mandibular toothrows of *L. fornicata* and the longer maxillary toothrow relative to mandibular toothrow in that species ($LTL = 1.32 + 0.884 \text{ UTL}$; $F = 61.65$, $p = 0.000$). D, Bivariate plot of height of coronoid process (CPH) and length of mandibular toothrow (LTL), illustrating the longer toothrow and relatively higher coronoid process of *L. fornicata* ($CPH = 2.37 + 0.154 \text{ LTL}$; $F = 1.12$, $p = 0.297$). The slopes of the regressions for plots A and D are not significantly different from zero.

for Costa Rican, Colombian, and Panamanian specimens to have shorter, broader skulls and longer forearms relative to Ecuadorian specimens. Along PC 3 (SB vs. CPH; not shown), the two species also overlap considerably.

Sexual dimorphism.—Among the *Lonchophyllini*, males and females are

generally similar in size and proportions, although geographically-constrained samples are still too small and uneven to have great confidence in statistical tests. Woodward & Timm (2006) found that their sample of female *Lonchophylla thomasi* exhibited a clear tendency to have a longer skull, narrower zygomatic breadth (but

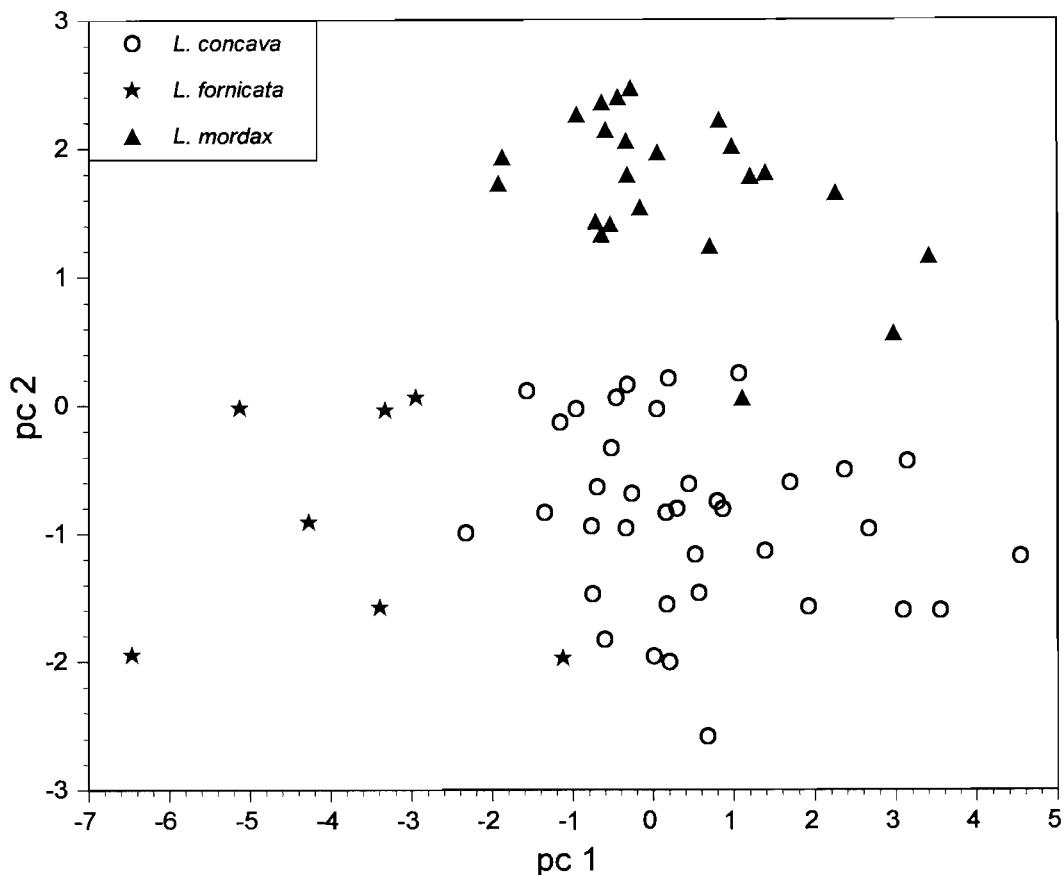

Fig. 4. Plot of scores on the first and second axes from PCA of eight variables measured from 37 *L. concava*, 7 *L. fornicata*, and 23 *L. mordax*. Factors loadings on PC 1 are negative (Table 2), so the largest individuals have the most negative scores on that axis.

Table 2.—Factor loadings for the first two axes from PCA of eight variables from 37 *L. concava*, 7 *L. fornicata*, and 23 *L. mordax* (Fig. 4).

equal or broader postorbital region), shorter coronoid process of the mandible, and longer forearm than males, but few of these differences were statistically significant. I found that female *Lonchophylla concava*, *L. fornicata*, *L. mordax*, and *Lionycteris spurrelli* show many of the same tendencies, with the exceptions that zygomatic breadth averages slightly greater in male *Lionycteris spurrelli* and is equal in male and female *L. mordax*; and the coronoid process tends to be higher in female *L. fornicata* (Table 1). Moreover, the difference in forearm length in *L. fornicata* is statistically significant, although this may be a result of the low sample sizes available. In multivariate

space (Fig. 5), male and female *L. concava* overlap considerably but exhibit different centers of distribution along PC 2, which reflect the tendency of females to have longer, narrower skulls and lower coronoïd processes (Table 3). A similarly subtle pattern of differentiation in multivariate space was reported between male and female *L. thomasi* (Woodman & Timm 2006).

Possible sexual differences in measurable characters are small (0–0.4 mm for cranial variables; 0.1–1.0 mm for length of forearm) and more often appear as general tendencies rather than as statistically significant distinctions. Their appearance across taxa, however, suggests that they may reflect real, if subtle, sexual

differences that are difficult to detect. Specifically, females generally tend to have a longer, narrower skull; a shorter coronoid process of the mandible; and a longer forearm, on average, than males.

Remarks.—The holotype and a second specimen of *L. fornicata* were captured by M. E. Thomas across from the village of Zabaletas along the east bank of the Rio Zabaletas, a tributary of the Río Anchicaya (M. E. Thomas 1972). This site is on the Pacific coastal plain in Premontane Rain Forest (IGAC 1988). Mean annual temperature in the region is ca. $25.5 \pm 2^{\circ}\text{C}$. There is a bimodal rainy season, and mean annual rainfall exceeds 7000 mm. The driest period is January–March. The study site encompassed a gravel bar at the edge of the river and extended inland across a lightly-forested flood plain and approximately 100 m into dense rain forest on an older river terrace (M. E. Thomas 1972). Additional details of the Zabaletas site were provided by Thomas (1972) and by Woodman & Timm (2006). Thomas captured 1646 individuals of 35 species of bats at Zabaletas from September 1966 through August 1967, with additional field work in June 1968 and January 1969. The total included six *Lonchophylla cadenai*, two *L. choocoana*, and two *L. fornicata*, indicating that these three species were syntopic at Zabaletas. *Lonchophylla* represented only 0.6% of captures, indicating that it was relatively uncommon to take any species of the genus here using traditional bat netting techniques.

All specimens of *L. fornicata* were collected on the Pacific side of the Andes in humid forest. A number of individuals are from about 225 m elevation at La Guayacana, also on the Pacific coastal plain of Colombia in Premontane Rain Forest (IGAC 1988). McCarthy et al. (2000) caught a male *L. fornicata* (CM 112585) at ca. 512 m elevation in a railroad tunnel near Lita, Imbabura Province, Ecuador, where it was apparently

roosting. Other species taken with it were *Balantiopteryx infusca*, *Carollia brevicauda*, and *Desmodus rotundus*. Lita, which is in Premontane Wet Forest, experiences a year-round wet season with an annual precipitation of 3000–4000 mm and a mean annual temperature of 18–22.4°C (Cañadas 1983).

Phylogenetic analysis.—Parsimony analysis of a data set of 64 characters (Table 4) yielded 16 shortest length trees (197 steps) with varied topologies. The strict consensus tree (Fig. 6) supports monophyly of the Lonchophyllini and identifies three terminal groups within the tribe, but deeper structure is obscured. One clade, identified in previous analyses (Dávalos & Jansas 2004, Woodman & Timm 2006), consists of *Lonchophylla choocoana*, *L. handleyi*, and *L. robusta*. In my analysis, these three taxa are linked with three other taxa in the form: (*L. mordax* (*Lionycteris spurrelli* (*Lonchophylla orcesi* (*L. choocoana* (*L. handleyi*, *L. robustaLonchophylla cadenai*, *L. pattoni*, and *L. thomasi*. The third grouping consists of *L. bokermanni*, *L. concava*, and *L. fornicata*. Few unambiguous characters support any of these branches, however.

Bootstrap analysis yielded a poorly resolved tree that was similar in many respects to that of Woodman & Timm (2006). Like that tree and the parsimony tree, it recovered a sister relationship between *L. handleyi* and *L. robusta* and identified the clade of *L. cadenai*, *L. pattoni*, and *L. thomasi*. It also linked *Platalina* and *Xeronycteris* as sister taxa and recovered *L. cadenai*, *L. pattoni*, and *L. thomasi* as a clade. Unfortunately, most bootstrap supports were quite low.

I had been hopeful that the additional character codings for *L. bokermanni* and the removal of a redundant character would provide a greater resolution of relationships than that reported by

Table 4.—Character matrix for phylogenetic analysis. Question marks indicate missing data; dashes indicate characters that are inapplicable.

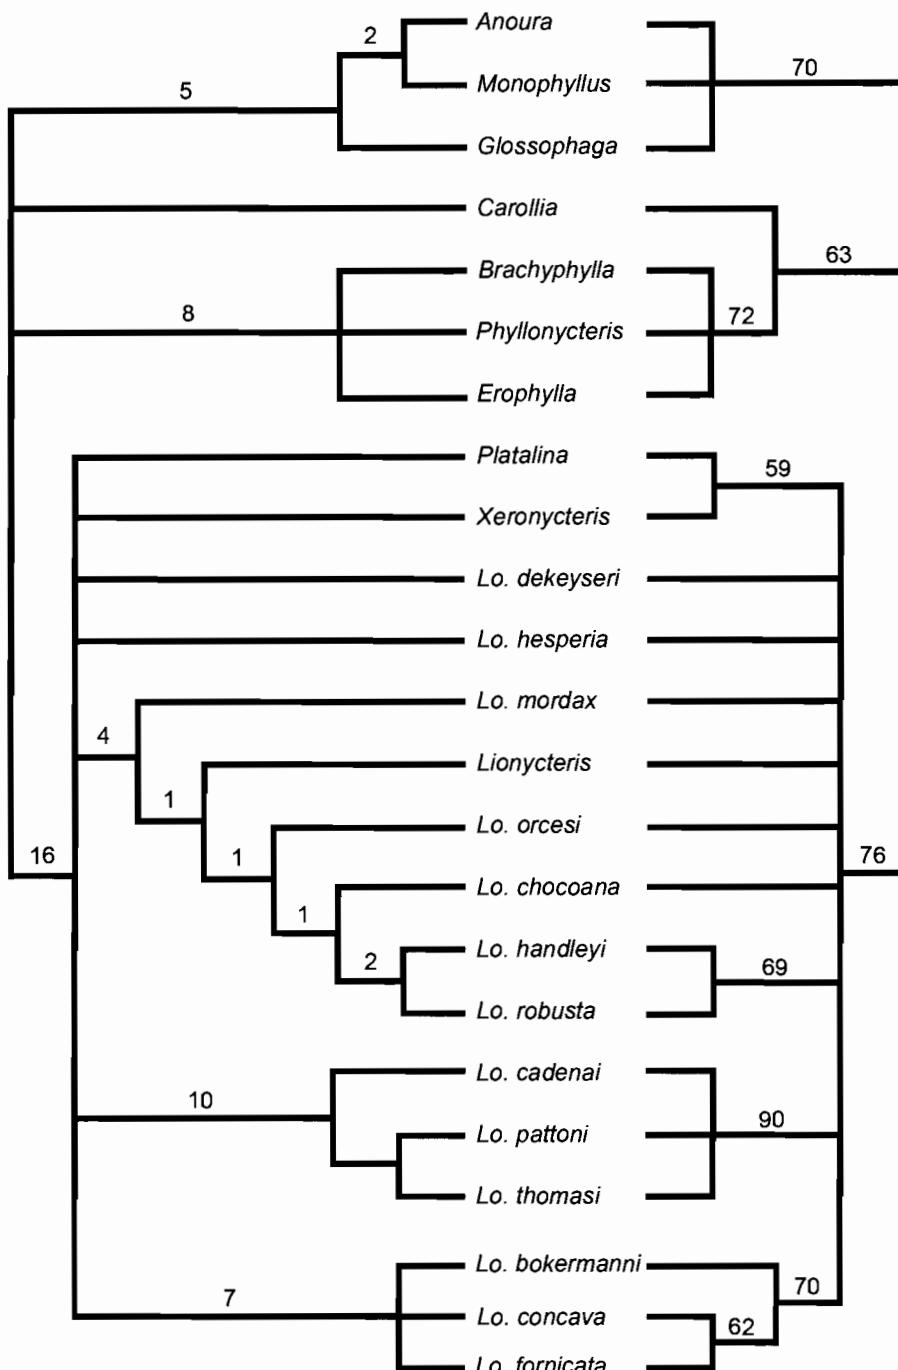

Fig. 6. Trees resulting from phylogenetic analysis of the Lonchophyllini using a data set of 64 characters. Strict consensus tree of 16 shortest length trees from parsimony analysis (left). Numbers of unambiguous changes is given above each branch. Tree statistics: length = 197; CI = 0.4721; RI = 0.6612; RC = 0.3122; HI = 0.5279; CI excluding uninformative characters = 0.4667; HI excluding uninformative characters = 0.5333; G-fit = -43.738; f-value = 2262; f-ratio = 0.7788. Bootstrap majority consensus tree (right). Bootstrap supports >50 are listed above each branch; branches with supports ≤ 50 are collapsed.

Woodman & Timm (2006). This did not turn out to be the case. Neither parsimony analysis nor bootstrap analysis was successful in identifying deeper structure within the *Lonchophyllini*, thus leaving unanswered the question of possibly paraphyly of *Lonchophylla* with respect to *Lionycteris*, *Platalina*, and/or *Xeronycteris*. Similarly, a deep division within *Lonchophylla*, hinted at by previous investigations (Dávalos & Jansa 2004, Woodman & Timm 2006), remains unconfirmed.

Acknowledgments

The following curators and collection staff graciously provided access to specimens under their care: Darrin Lunde, Nancy B. Simmons, Robert S. Voss, and Eileen Westwig (AMNH); Suzanne B. McLaren (CM); Lawrence R. Heaney, Bruce D. Patterson, and William S. Stanley (FMNH); Robert M. Timm (KU); Jim Dines (LACM); Mark S. Hafner (LSUMZ); Joseph A. Cook (MSB); Barbara Lundrigan (MSU); Heath Garner and Robert J. Baker (TTU). Alfred L. Gardner, Roy McDiarmid, Ron H. Pine, Robert P. Reynolds, and Nancy B. Simmons kindly provided valuable comments on previous versions of this manuscript.

Platalina genovensium (1).—PERU: Arequipa: Caravelí (USNM 268765).

Appendix II: Character Codings For Phylogenetic Analysis

External characters:

1. Pelage: differentiated into under hair and over hair (0); lacking over hair (1).
2. Majority of scale margins on hairs: entire (0); toothed (1).
3. Dorsal fur: unicolored (0); bicolored (1).
4. Genal vibrissae: absent (0); with single vibrissa in each cluster (1); two vibrissae in each cluster (2).
5. Interramal vibrissae: one vibrissa (0); two vibrissae (1); three vibrissae (2).
6. Central rib of noseleaf: absent (0); restricted to proximal portion of spear (1); extending to distal tip of spear (2).
7. Internarial region: smooth (0); with line of papillae (1).
8. Chin: without central cleft (0); with central cleft (2).

Hyoid musculature and tongue:

9. *M. ceratohyoideus*: does not insert on stylohyal (0); or partly inserts on stylohyal (1).
10. *M. genioglossus*: inserts into ventral surface of tongue along more than half of its length (0); insert into posterior half to third of ventral surface of tongue (1); inserts into posterior quarter of ventral surface of tongue (2).
11. Anterolateral slip of *M. sphincter colli profundus*: present (0); absent (1).
12. *M. crocopharyngeus*: consists of a single large slip (0); two slips (1); three slips (2); more than three slips (3).
13. Lingual sulci: absent (0); present on lateral surface of tongue (1).
14. Hairlike papillae: confined to lateral margin of distal third of tongue, with a single line of papillae extending approximately to lateral circumvallate papillae (0); distributed around lateral margin and dorsum of distal third of tongue (1).
15. Hairlike papillae of tongue: fleshy and conical (0); fleshy and conical with filamentous tips (1); cylindrical with ellipse-shaped distal end (2).
16. Medial-posterior patch of anteriorly directed mechanical papillae of tongue: always absent (0); present in some individuals (1); always present (2).
17. Basketlike papillae of tongue: absent (0); present (1).
18. Lingual papillae anterior to main papillae: three small papillae (0); one papilla (1); no papilla (2).

19. Primary horny papillae: flanked by a pair of smaller horny papillae (0); variable (1); no smaller papillae (2).

20. Lingual arteries: paired, lingual veins not enlarged (0); single midline artery, lingual veins enlarged (1).

Restriction sites:

21. Restriction site 50 of transcribed portion of rDNA complex: present (0); absent (1).
22. Restriction site 53: absent (0); present (1).

Skull:

23. Zygomatic arch: complete (0); incomplete (1); polymorphic within species (2).
24. Length of skull (relative to least postorbital breadth): short [mean GLS/PO < 4.8] (0); long [mean GLS/PO = 5.0–5.5] (1); very long [mean GLS/PO > 5.9] (2).
25. Length of rostrum relative to length of braincase: short—measured from position of cribriform plate, rostrum less than 34% length of skull (0); long, 36–38% (1); very long, >39% (2).
26. Rostrum: slightly inflated (uninflated) (0); distinctly inflated (1).
27. Postorbital region: uninflated (0); slightly inflated (1); moderately inflated (2); strongly inflated (3).
28. Postorbital processes: absent (0); present (1).
29. Posterior margin of infraorbital foramen: within margin of rostrum (0); forms laterally-projecting lip (1).
30. Position of posterior margin of infraorbital foramen: above posterior root of P3 (0); between P3 and P4 (1); above anterior root of P4 (2); between roots of P4 (3); above posterior root of P4 (4); between P4 and M1 (5); above anterior root of M1 (6); between roots of M1 (7).
31. Deep midline depression on posterior palate: absent (0); present (1).
32. Length of palate immediately posterior to M3: short, ≤anterior-posterior length of M3 (0); long, > length of M3 (1).
33. Shape of mesopterygoid fossa: long, open, U-shaped or W-shaped anteriorly (0); short, acute V-shaped anteriorly (1).
34. Medial projection of palate into mesopterygoid fossa: present (0); absent (1).
35. Pterygoid processes: slender, uninflated (0); inflated (1).
36. Basisphenoid pits: very shallow (0); shallow (1); deep (2).
37. Septum between basisphenoid pits: very broad (0); broad (1); narrow (2).
38. Posterolateral border of palate: concave (0); convex, projecting into zygomatic space (1).

39. Position of posterior border of palate: posteromedial edge of palate well anterior to optic foramen (0); just anterior to or at posterior border of optic foramen (1); posterior to optic foramen and near anterior end of sphenoidal fissure (2); well posterior to optic foramen and near middle of sphenoidal fissure (3).
40. Coronoid process: very high (0); high (1); low [articular condyle nearly at level of tip of coronoid process] (2).
41. Height of articular condyle: about level with mandibular toothrow (0); above level of mandibular toothrow (1).

Upper dentition:

42. I1: distinctly larger than I2 (0); about equal in size with I2 (1).
43. First upper incisors: not projecting anteriorly (0); projecting slightly anteriorly (1); projecting greatly anteriorly (2).
44. Gap between I1 and I2: narrow (0); broad (1).
45. Anterior edge of canine: rounded (0); flattened (1); grooved by wear against lower canine (2).
46. Parastyle on P3: low, but distinct (0); very low, indistinct (1).
47. Paracone on P4: low (0); high (1).
48. Lingual cusp on P4: rooted lingual expansion of cingulum (0); obvious lingual cusp (1); lingual cusp absent or reduced (2).
49. Ectoloph of M1–M2: present (0); absent (1).
50. M1 and M2: in contact (0); not in contact diastema present (1).

51. Parastyle on M1 and M2: distinct and anterior to paracone (0); present, not anterior to paracone (1); absent (2).
52. Mesostyle M1 and M2: absent (0); present (1).
53. Metastyle on M1: reduced or absent (0); present (1).
54. Postprotocrista on M1, M2, and M3: present (0); reduced or absent (1).
55. Hypocone on M1, M2: present (0); absent (1).
56. Posthypocrista on M1, M2: present (0); absent (1).
57. Position of M3: located entirely posterior to anterior edge of base of zygomatic process (0); part of M3 anterior to base of zygomatic process (1); M3 entirely anterior to zygomatic process (2); M3 much anterior to zygomatic process (3).

Lower dentition:

58. Lower incisors: not trifid (0); trifid (1).
59. Gap between i2 and cl: absent, teeth essentially overlapping (0); small (1); large, at least as long as length of i2 (2).
60. Cingulum on cl: present (0); absent (1).
61. posterior cusp (hypoconid) on p2: present (0); absent (1).
62. Elongate labial cusp (metacristid) on p3: absent (0); present (1).
63. Entoconid on m1, m2, and m3: present (0); absent (1).
64. Strong pre-entoconid extending anteriorly from entoconid on m1–m2: absent (0); present (1).
